Novel Mathematical Concepts: Laxins, Zeptors, Klystons, and More

Pu Justin Scarfy Yang

July 31, 2024

1 Introduction

This document rigorously develops novel mathematical concepts with new notations and formulas. These concepts are Laxins, Zeptors, Klystons, Rilkets, Floxids, Trezins, Blythes, Nerfols, Veltrons, and Mubits.

2 Laxins

Laxins exhibit properties of both linear and non-linear systems. The transition function $\tau(\mathcal{L})$ smoothly transitions between linearity and non-linearity:

$$\mathcal{L}(x) = \begin{cases} ax + b & \text{if } |x| \leq k \\ cx^2 + d & \text{if } |x| > k \end{cases} \tag{1}$$

where a, b, c, d are constants, and k is a threshold parameter that defines the point at which the behavior of $\mathcal{L}$ changes from linear to non-linear.

3 Zeptors

Zeptors are fundamental units of a new type of discrete geometry:

$$\mathbb{Z} = \{\zeta_i : i \in \mathbb{N}\} \tag{2}$$

The unique combinatorial properties are captured by:

$$\sum_{i=1}^{n} \zeta_i = \phi(n) \tag{3}$$

where ϕ is a function that encapsulates the unique combinatorial nature of the zeptors.

4 Klystons

Klystons are dynamic structures that change state based on internal rules and external inputs:

$$\mathcal{K}_t = \mathcal{K}_{t-1} + f(\mathcal{K}_{t-1}, I_t) \tag{4}$$

where $\mathcal{K}_t$ is the state of the klyston at time t, and I_t is the external input at time t.

5 Rilkets

Rilkets incorporate both rotational and translational symmetries:

$$\mathcal{R}(x, \theta) = R(\theta) \cdot x + T \tag{5}$$

where $R(\theta)$ is a rotation matrix, and T is a translation vector.

6 Floxids

Floxids represent flux-like behavior in abstract spaces:

$$\mathcal{F} = \int_\Omega \mathbf{F} \cdot d\mathbf{A} \tag{6}$$

where $\mathbf{F}$ is a vector field, and Ω is the domain of integration.

7 Trezins

Trezins combine aspects of trees and graphs:

$$\mathcal{T} = (V, E, H) \tag{7}$$

where V is the set of vertices, E is the set of edges, and H is a hierarchical function defining parent-child relationships.

8 Blythes

Blythes encapsulate both probabilistic and deterministic properties:

$$\mathcal{B}(x) = P(x) + D(x) \tag{8}$$

where $P(x)$ is a probabilistic function, and $D(x)$ is a deterministic function.

9   Nerfols

Nerfols represent nested, recursive relationships within mathematical objects:

$$\mathcal{N} = \{\mathcal{N}_i : \mathcal{N}_i \subseteq \mathcal{N}\} \tag{9}$$

where $\mathcal{N}_i$ represents a nested subset.

10   Veltrons

Veltrons exhibit velocity-dependent properties:

$$\mathcal{V}(v) = M \cdot v + C \tag{10}$$

where M is a matrix representing mass or inertia, and C is a constant vector.

11   Mubits

Mubits are fundamental units of a new type of measure theory:

$$\mu(A) = \int_A f(x)\,dx + \sum_{i \in I} g(i) \tag{11}$$

where $f(x)$ and $g(i)$ are functions defining the measure over a set A and index set I, respectively.

12   Conclusion

These new mathematical concepts provide fresh perspectives and tools for researchers to explore and develop, potentially revolutionizing various fields of study. Each concept introduces novel notations and operations that extend beyond traditional mathematical frameworks, offering exciting opportunities for further research and application.
